1.1 Classification of Elements

One of the simplest methods for classifying elements is to divide them into three categories:

✚ Metals

- Good conductors of heat and electricity.
- Malleable and ductile with a shiny appearance.
- Found on the left and center of the periodic table (e.g., Fe, Cu).

✚ Non-Metals

- Poor conductors of heat and electricity.
- Brittle in solid form and often exist as gases or dull solids.
- Found on the right side of the periodic table (e.g., O, N).

✚ Metalloids

- Exhibit properties of both metals and non-metals.
- Found along the "stair-step" line in the periodic table (e.g., Si, Br).

1.2 The Periodic Table

The periodic table is a systematic arrangement of chemical elements organized by their atomic number, electron configuration, and recurring chemical properties. It is a fundamental tool in chemistry, providing a clear framework for understanding the relationships between elements and predicting their behavior.

The idea of arranging the elements into a periodic table had been considered by many chemists, but either the data to support the idea were insufficient or the classification scheme was incomplete. Mendeleev and Meyer organized the elements in order of atomic weight and then

identified families of elements with similar properties. By arranging these families in rows or columns, and by considering similarities in chemical behavior as well as atomic weight, Mendeleev found vacancies in the table and was not able to predict the properties of several elements (Gallium, Scandium, Germanium, Polonium) that had not yet been discovered.

Periodic Table of the Elements

Period	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
1	1 H 1.008 hydrogen																	2 He 4.003 helium
2	3 Li 6.94 lithium	4 Be 9.012 beryllium											5 B 10.81 boron	6 C 12.01 carbon	7 N 14.01 nitrogen	8 O 16.00 oxygen	9 F 19.00 fluorine	10 Ne 20.18 neon
3	11 Na 22.99 sodium	12 Mg 24.31 magnesium											13 Al 26.98 aluminum	14 Si 28.09 silicon	15 P 30.97 phosphorus	16 S 32.06 sulfur	17 Cl 35.45 chlorine	18 Ar 39.95 argon
4	19 K 39.10 potassium	20 Ca 40.08 calcium	21 Sc 44.96 scandium	22 Ti 47.87 titanium	23 V 50.94 vanadium	24 Cr 52.00 chromium	25 Mn 54.94 manganese	26 Fe 55.85 iron	27 Co 58.93 cobalt	28 Ni 58.69 nickel	29 Cu 63.55 copper	30 Zn 65.38 zinc	31 Ga 69.72 gallium	32 Ge 72.63 germanium	33 As 74.92 arsenic	34 Se 78.97 selenium	35 Br 79.90 bromine	36 Kr 83.80 krypton

Atomic number → 1

Symbol → **H**

Atomic mass → 1.008

Name → hydrogen

Color Code

 Metal	Solid
 Metalloid	Liquid
 Nonmetal	Gas

1.3 Structure of the Periodic Table

❖ Groups (Columns):

- There are 18 vertical columns called groups.
- Elements in the same group share similar chemical properties because they have the same number of valence electrons.
- Examples:
 - Group 1: Alkali metals (e.g., Lithium - Li).
 - Group 17: Halogens (e.g., Fluorine - F).
 - Group 18: Noble gases (e.g., Helium - He).

❖ Periods (Rows):

- There are 7 horizontal rows called periods.
- The period number corresponds to the number of electron shells in the elements of that row.

❖ Blocks:

- The table is divided into four main blocks based on the electron configuration of the elements:
 - **s-block**: Groups 1-2.
 - **p-block**: Groups 13-18.
 - **d-block**: Transition metals.
 - **f-block**: Lanthanides and actinides.

Periodic Table of the Elements

Group 1	2	Main group elements										13	14	15	16	17	18
Alkali metals	Alkaline earth metals	Transition metals												P n i c t o g e n s	C h a l c o g e n s	H a l o g e n s	N o b l e g a s e s
		3	4	5	6	7	8	9	10	11	12						
		Lanthanides															
		Actinides															

1.4 Electron Configuration

Electron configuration refers to the arrangement of electrons in an atom's orbitals around its nucleus. It determines the chemical and physical properties of an element. The electrons are distributed in energy levels or shells, which are further divided into subshells (**s**, **p**, **d**, and **f**).

Examples:

H₁: **1S¹**

Li₃: **1S² 2S¹**

Na₁₁: **1S² 2S² 2P⁶ 3S¹**

K₁₉: **1S² 2S² 2P⁶ 3S² 3P⁶ 4S¹**

Rh₃₇: **1S² 2S² 2P⁶ 3S² 3P⁶ 4S² 3d¹⁰ 4P⁶ 5S¹**

Cs₅₅: **1S² 2S² 2P⁶ 3S² 3P⁶ 4S² 3d¹⁰ 4P⁶ 5S² 4d¹⁰ 5P⁶ 6S¹**

Fr₈₇: **1S² 2S² 2P⁶ 3S² 3P⁶ 4S² 3d¹⁰ 4P⁶ 5S² 4d¹⁰ 5P⁶ 6S² 5d¹⁰ 4f¹⁴ 6P⁶ 7S¹**

1.5 Principles Governing Electron Configuration

1. Aufbau Principle:

- Electrons fill the **lowest energy orbitals first** before moving to **higher energy levels**.
- Orbital filling order: $1s, 2s, 2p, 3s, 3p, 4s, 3d, 4p, 5s, \dots$

2. Pauli Exclusion Principle:

- Each **orbital can hold a maximum of 2 electrons** with opposite spins.

3. Hund's Rule:

- In orbitals of equal energy (like the three p-orbitals), **electrons fill each orbital singly before pairing up**.

1.6 The Periodic table properties

1.6.1 Atomic Radius

Definition: The atomic radius is the distance from the nucleus to the outermost electron, or it can be described as half the distance between the centers of two adjacent atoms of the same element in a molecule.

- **Decreases** across a **period** (left to right) due to increasing nuclear charge.
- **Increases** down a **group** as more electron shells are added.

1.6.2 Ionization Energy

Definition: The ionization energy, E_I , of an atom/ion is the minimum energy, which is required to remove an electron of an atom. The unit of ionization energy is kJ/mol.

- **Increases** across a **period** because atoms hold their electrons more tightly.
- **Decreases** down a **group** as electrons are farther from the nucleus.

1.6.3 Electronegativity

Definition: The electronegativity, χ , describes the ability of an atom to attract electrons towards.

- **Increases** across a **period** as the tendency to attract electrons in a bond strengthens.
- **Decreases** down a **group** due to increased distance from the nucleus.

Problem: Put in order of largest to smallest: F, Ar, Sr, and Cs.

Solution: $\text{Cs} > \text{Sr} > \text{Ar} > \text{F}$

1.7 Shielding

Each electron act as a shell for another electron and reducing the attraction between the nucleus and further electrons.

Slater's Rules: In 1930, J. C. Slater proposed a set of empirical rules to semiquantify the concept of effective nuclear charge. He proposed a formula that related

How can we calculate the effective charge of the nucleus?

$$Z_{\text{eff}} = Z - S$$

1. The electrons are written in groups as follows:

1s | 2s 2p | 3s 3p | 3d | 4s 4p | 4d | 4f | 5s 5p | 5d |....

2. All electrons in orbitals of greater principal quantum number

(At $n+1$) contribute zero.

3. for ns or np valence electrons:

a- Electrons in the same ns, np group (same principal quantum number) contributes (0.35).

b- Electrons in the (n-1) principal group contribute (0.85).

c- Electrons in the (n-2) or lower groups contribute (1.00).

4- For nd and nf valence electrons:

a- Electrons in the same nd and nf group contribute (0.35).

b- Electrons in the groups to the left contribute (1.00).

Example: to calculate the effective nuclear charge on one of the 2p Electrons in the oxygen atom ($1S^2S^2P^4$), we first find the screening (or Shielding) constant:

$$S = (2 \times 0.85) + (5 \times 0.35) = 3.45$$

$$Z_{\text{eff}} = Z - S$$

$$= 8 - 3.45$$

$$= 4.55$$
