

11

Compressibility of Soil

A stress increase caused by the construction of foundations or other loads compresses soil layers. The compression is caused by (a) deformation of soil particles, (b) relocations of soil particles, and (c) expulsion of water or air from the void spaces. In general, the soil settlement caused by loads may be divided into three broad categories:

1. *Elastic settlement* (or *immediate settlement*), which is caused by the elastic deformation of dry soil and of moist and saturated soils without any change in the moisture content. Elastic settlement calculations generally are based on equations derived from the theory of elasticity.
2. *Primary consolidation settlement*, which is the result of a volume change in saturated cohesive soils because of expulsion of the water that occupies the void spaces.
3. *Secondary consolidation settlement*, which is observed in saturated cohesive soils and is the result of the plastic adjustment of soil fabrics. It is an additional form of compression that occurs at constant effective stress.

This chapter presents the fundamental principles for estimating the elastic and consolidation settlements of soil layers under superimposed loadings.

The total settlement of a foundation can then be given as

$$S_T = S_c + S_s + S_e$$

where S_T = total settlement

S_c = primary consolidation settlement

S_s = secondary consolidation settlement

S_e = elastic settlement

When foundations are constructed on very compressible clays, the consolidation settlement can be several times greater than the elastic settlement.

ELASTIC SETTLEMENT

11.1

Contact Pressure and Settlement Profile

Elastic, or immediate, settlement of foundations (S_e) occurs directly after the application of a load without a change in the moisture content of the soil. The magnitude of the contact

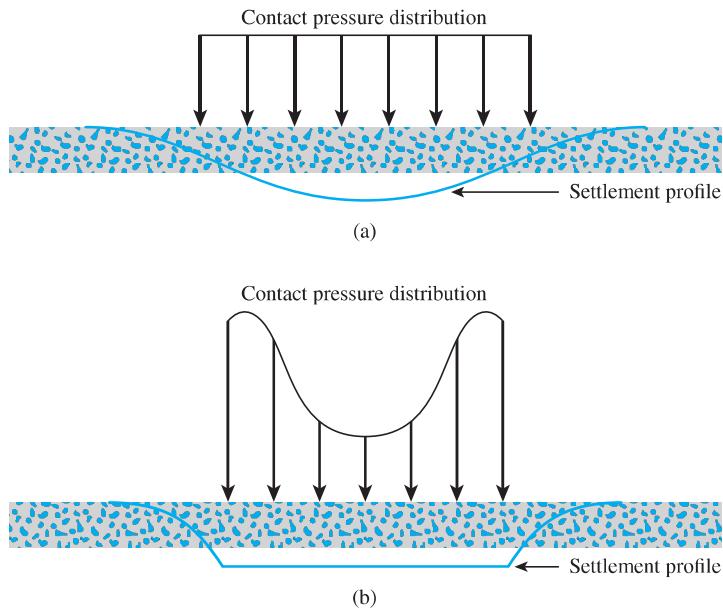

Figure 11.1
Elastic settlement profile and contact pressure in clay:
(a) flexible foundation; (b) rigid foundation

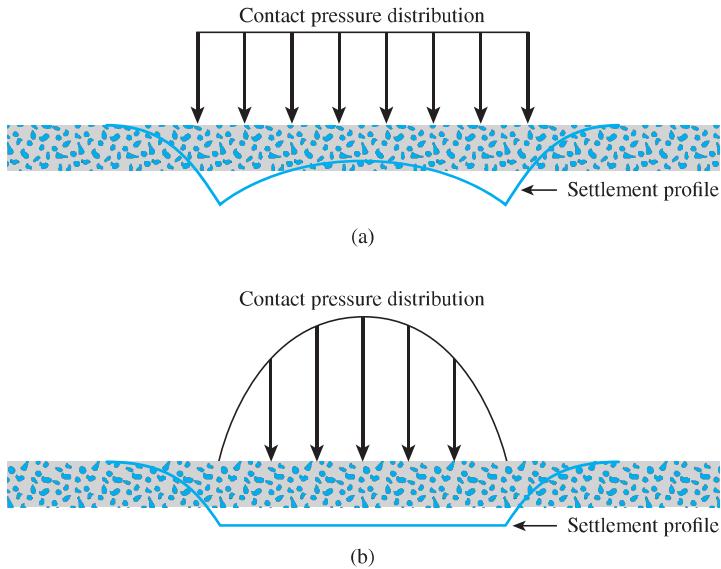

settlement will depend on the flexibility of the foundation and the type of material on which it is resting.

In Chapter 10, the relationships for determining the increase in stress (which causes elastic settlement) due to the application of line load, strip load, embankment load, circular load, and rectangular load were based on the following assumptions:

- The load is applied at the ground surface.
- The loaded area is *flexible*.
- The soil medium is homogeneous, elastic, isotropic, and extends to a great depth.

In general, foundations are not perfectly flexible and are embedded at a certain depth below the ground surface. It is instructive, however, to evaluate the distribution of the contact pressure under a foundation along with the settlement profile under idealized conditions. Figure 11.1a shows a *perfectly flexible* foundation resting on an elastic material such as saturated clay. If the foundation is subjected to a uniformly distributed load, the contact pressure will be uniform and the foundation will experience a sagging profile. On the other hand, if we consider a *perfectly rigid* foundation resting on the ground surface subjected to a uniformly distributed load, the contact pressure and foundation settlement profile will be as shown in Figure 11.1b: the foundation will undergo a uniform settlement and the contact pressure will be redistributed.

The settlement profile and contact pressure distribution described are true for soils in which the modulus of elasticity is fairly constant with depth. In the case of cohesionless sand, the modulus of elasticity increases with depth. Additionally, there is a lack of lateral confinement on the edge of the foundation at the ground surface. The sand at the edge of a flexible foundation is pushed outward, and the deflection curve of the foundation takes a concave downward shape. The distributions of contact pressure and the settlement profiles of a flexible and a rigid foundation resting on sand and subjected to uniform loading are shown in Figures 11.2a and 11.2b, respectively.

**Figure 11.2**

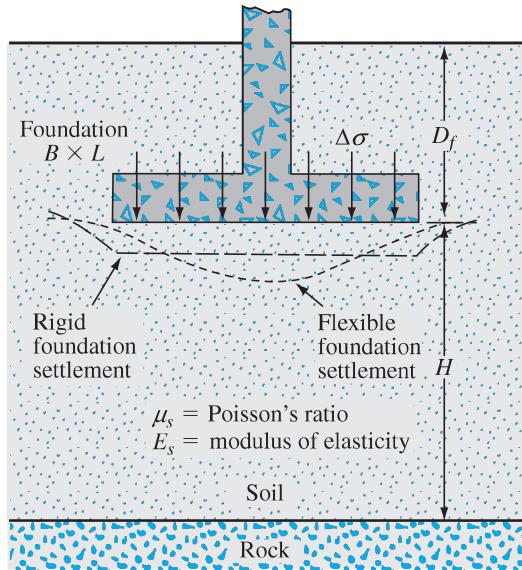

Elastic settlement profile and contact pressure in sand:
(a) flexible foundation; (b) rigid foundation

11.2

Relations for Elastic Settlement Calculation

Figure 11.3 shows a shallow foundation subjected to a net force per unit area equal to $\Delta\sigma$. Let the Poisson's ratio and the modulus of elasticity of the soil supporting it be μ_s and E_s , respectively. Theoretically, if the foundation is perfectly flexible, the settlement may be expressed as

$$S_e = \Delta\sigma(\alpha B') \frac{1 - \mu_s^2}{E_s} I_s I_f \quad (11.1)$$

**Figure 11.3** Elastic settlement of flexible and rigid foundations

where $\Delta\sigma$ = net applied pressure on the foundation

μ_s = Poisson's ratio of soil

E_s = average modulus of elasticity of the soil under the foundation measured from $z = 0$ to about $z = 4B$

B' = $B/2$ for center of foundation

= B for corner of foundation

I_s = shape factor (Steinbrenner, 1934)

$$= F_1 + \frac{1 - 2\mu_s}{1 - \mu_s} F_2 \quad (11.2)$$

$$F_1 = \frac{1}{\pi} (A_0 + A_1) \quad (11.3)$$

$$F_2 = \frac{n'}{2\pi} \tan^{-1} A_2 \quad (11.4)$$

$$A_0 = m' \ln \frac{(1 + \sqrt{m'^2 + 1}) \sqrt{m'^2 + n'^2}}{m'(1 + \sqrt{m'^2 + n'^2 + 1})} \quad (11.5)$$

$$A_1 = \ln \frac{(m' + \sqrt{m'^2 + 1}) \sqrt{1 + n'^2}}{m' + \sqrt{m'^2 + n'^2 + 1}} \quad (11.6)$$

$$A_2 = \frac{m'}{n' \sqrt{m'^2 + n'^2 + 1}} \quad (11.7)$$

$$I_f = \text{depth factor (Fox, 1948)} = f\left(\frac{D_f}{B}, \mu_s, \text{and } \frac{L}{B}\right) \quad (11.8)$$

α = factor that depends on the location on the foundation where settlement is being calculated

- For calculation of settlement at the *center* of the foundation:

$$\alpha = 4$$

$$m' = \frac{L}{B}$$

$$n' = \frac{H}{\left(\frac{B}{2}\right)}$$

- For calculation of settlement at a *corner* of the foundation:

$$\alpha = 1$$

$$m' = \frac{L}{B}$$

$$n' = \frac{H}{B}$$

The variations of F_1 and F_2 [Eqs. (11.3) and (11.4)] with m' and n' given in Tables 11.1 and 11.2. Also the variation of I_f with D_f/B and μ_s is given in Table 11.3. Note that when $D_f = 0$, the value of $I_f = 1$ in all cases.

Table 11.3 Variation of I_f with L/B and D_f/B

L/B	D_f/B	I_f		
		$\mu_s = 0.3$	$\mu_s = 0.4$	$\mu_s = 0.5$
1	0.5	0.77	0.82	0.85
	0.75	0.69	0.74	0.77
	1	0.65	0.69	0.72
2	0.5	0.82	0.86	0.89
	0.75	0.75	0.79	0.83
	1	0.71	0.75	0.79
5	0.5	0.87	0.91	0.93
	0.75	0.81	0.86	0.89
	1	0.78	0.82	0.85

The elastic settlement of a *rigid foundation* can be estimated as

$$S_{e(\text{rigid})} \approx 0.93 S_{e(\text{flexible, center})} \quad (11.9)$$

Due to the nonhomogeneous nature of soil deposits, the magnitude of E_s may vary with depth. For that reason, Bowles (1987) recommended using a weighted average value of E_s in Eq. (11.1) or

$$E_s = \frac{\sum E_{s(i)} \Delta z}{\bar{z}} \quad (11.10)$$

Where $E_{s(i)}$ = soil modulus of elasticity within a depth Δz
 $\bar{z} = H$ or $5B$, whichever is smaller

Representative values of the modulus of elasticity and Poisson's ratio for different types of soils are given in Tables 11.4 and 11.5, respectively.

Table 11.4 Representative Values of the Modulus of Elasticity of Soil

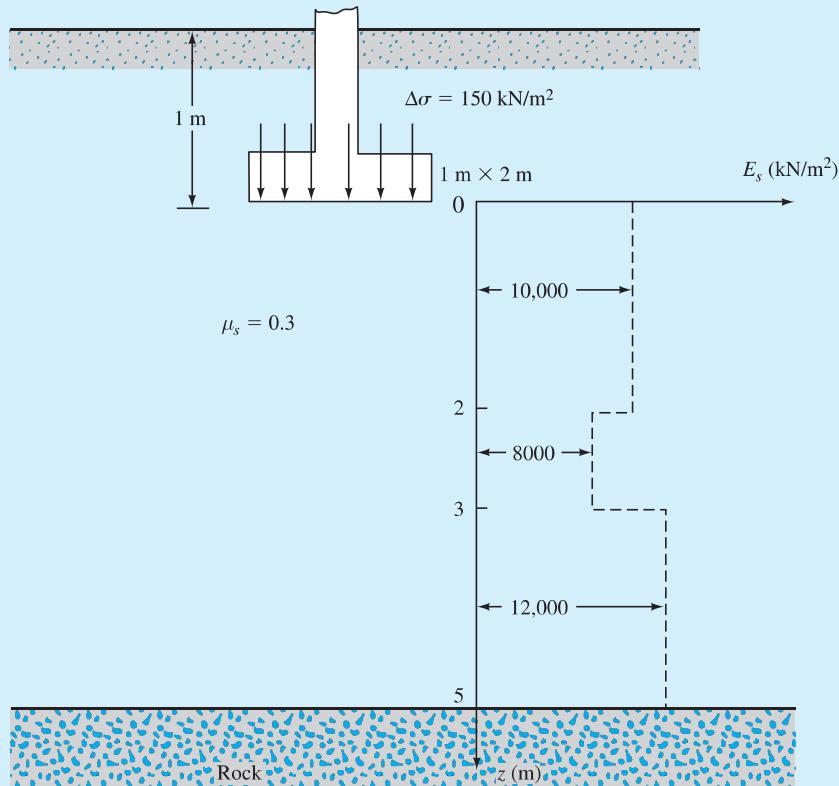

Soil type	E_s	
	kN/m²	lb/in.²
Soft clay	1,800–3,500	250–500
Hard clay	6,000–14,000	850–2,000
Loose sand	10,000–28,000	1,500–4,000
Dense sand	35,000–70,000	5,000–10,000

Table 11.5 Representative Values of Poisson's Ratio

Type of soil	Poisson's ratio, μ_s
Loose sand	0.2–0.4
Medium sand	0.25–0.4
Dense sand	0.3–0.45
Silty sand	0.2–0.4
Soft clay	0.15–0.25
Medium clay	0.2–0.5

Example 11.1

A rigid shallow foundation $1 \text{ m} \times 2 \text{ m}$ is shown in Figure 11.4. Calculate the elastic settlement at the center of the foundation.

**Figure 11.4**

Solution

Given: $B = 1 \text{ m}$ and $L = 2 \text{ m}$. Note that $\bar{z} = 5 \text{ m} = 5B$. From Eq. (11.10),

$$\begin{aligned} E_s &= \frac{\sum E_{s(i)} \Delta z}{\bar{z}} \\ &= \frac{(10,000)(2) + (8,000)(1) + (12,000)(2)}{5} = 10,400 \text{ kN/m}^2 \end{aligned}$$

For the *center of the foundation*,

$$\begin{aligned} \alpha &= 4 \\ m' &= \frac{L}{B} = \frac{2}{1} = 2 \\ n' &= \frac{H}{\left(\frac{B}{2}\right)} = \frac{5}{\left(\frac{1}{2}\right)} = 10 \end{aligned}$$

From Tables 11.1 and 11.2, $F_1 = 0.641$ and $F_2 = 0.031$. From Eq. (11.2),

$$\begin{aligned} I_s &= F_1 + \frac{2 - \mu_s}{1 - \mu_s} F_2 \\ &= 0.641 + \frac{2 - 0.3}{1 - 0.3} (0.031) = 0.716 \end{aligned}$$

Again, $\frac{D_f}{B} = \frac{1}{1} = 1$, $\frac{L}{B} = 2$, $\mu_s = 0.3$. From Table 11.3, $I_f = 0.71$. Hence,

$$\begin{aligned} S_{e(\text{flexible})} &= \Delta\sigma(\alpha B) \frac{1 - \mu_s^2}{E_s} I_s I_f \\ &= (150) \left(4 \times \frac{1}{2} \right) \left(\frac{1 - 0.3^2}{10,400} \right) (0.716)(0.71) = 0.0133 \text{ m} = 13.3 \text{ mm} \end{aligned}$$

Since the foundation is rigid, from Eq. (11.9),

$$S_e(\text{rigid}) = (0.93)(13.3) = 12.4 \text{ mm}$$

CONSOLIDATION SETTLEMENT

11.3

Fundamentals of Consolidation

When a saturated soil layer is subjected to a stress increase, the pore water pressure is increased suddenly. In sandy soils that are highly permeable, the drainage caused by the increase in the pore water pressure is completed immediately. Pore water drainage is accompanied by a reduction in the volume of the soil mass, which results in settlement. Because of rapid drainage of the pore water in sandy soils, elastic settlement and consolidation occur simultaneously.

When a saturated compressible clay layer is subjected to a stress increase, elastic settlement occurs immediately. Because the hydraulic conductivity of clay is significantly
