Alkynes

By

Dr. Assel Amer Hadi

Alkynes

- 1. Alkyne group have a triple bond between two carbon atoms.
- 2. Two hydrogen atoms have been removed from each of two adjacent carbon atoms, thereby allowing the two adjacent carbon atoms to form a triple bond.
- 3. General formula is: CnH2n-2
- 4. Begins with ethyne (acetylene)
- 5. For Example: C2H2 H— $C \equiv C$ —H

Ethyne (acetylene)

Classification of Alkyne

Alkyne are further classified as terminal or non-terminal alkynes according as the triple bond is present at the carbon chain or within the carbon chain.

Terminal alkynes

 $CH_3 C \equiv CH \text{ (Propyne)} CH_3 CH_2 C \equiv CH \text{ (1-Butyne)}$

Non-Terminal alkynes

CH₃ C≡C CH₃ (2-Butyne), CH₃ C≡CCH₂ CH₃ (2-Pentyne)

IUPAC Rules for Alkyne Nomenclature

The IUPAC rules for naming alkynes are:

- 1) The same as those for alkenes except that the ending is (-yne).
- 2) The (yne) suffix (ending) indicates an alkyne or cycloalkyne.
- 3) The longest chain chosen for the root name must include <u>both</u> <u>carbon atoms of the triple bond</u>.
- 4) The root chain must be numbered <u>form the end nearest a triple bond carbon atom</u>. If the triple bond is in the center of the chain the nearest substituent rule is used to determine the end where numbering starts.

- 5) The smaller of the two numbers designating the carbon atoms of the triple bond is used as the triple bond locator.
- 6) If several multiple bonds are present, each must be assigned a locator number.

The following examples illustrate the rules:

$$H-C \Longrightarrow C-C_2H_5$$
 $CH_3-C \Longrightarrow C-CH_3$ 1-butyne 2- butyne

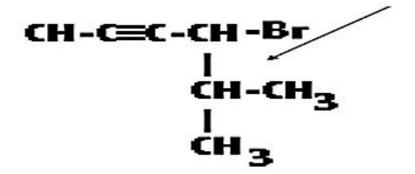

$$CH_3 - C \equiv C - C - CH_3$$

$$CH_3 - C \equiv C - C - CH_3$$

$$CH_3 - C \equiv C - CH_3$$

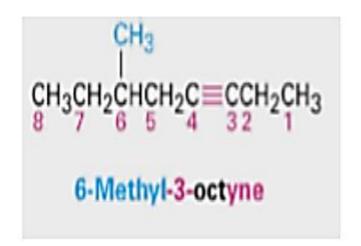

$$CH_3 - CH_3$$

CH₃C≡CH methylacetylene (propyne)

4bromo-5-methyl-2-hexyne

3-methyl-1-pentyne

Reaction

Most of the reactions of a Hornes are similar to those of alkenes.

The same reagents that add to carbon-carbon double bond also add to carbon-carbon triple bond. But it is possible to add two molecules of reagent to each alkyne.

1-Addition of Halogens (Halogenation)

CH₃-CH₂- C
$$\equiv$$
CH+Br₂ — CH₃-CH₂-CBr = CHBr
CH₃-CH₂- CBr = CHBr+Br₂ — CH₃-CH₂-CBr₂-CHBr₂
1-butyne — 1,2-dibromo-1-butyne \rightarrow 1,1,2,2-tetrabromobutane

2- Addition of Dihydrogen (Hydrogenation)

The addition of H2 to alkyne is obtain by add the hydrogen gas to alkyne with uses the metal (Ni ,Pd , ...) catalysis to give alkene in first step an alkane in the second step

$$CH_3-C \equiv CH \xrightarrow{H_2} CH_3-CH = CH_2 \xrightarrow{H_2} CH_3-CH_2-CH_3$$
propyne \longrightarrow propene \longrightarrow propane

3- Addition of Halogen halide (Hydrohalogenation)

The addition of HX is obtain according to Markovnikov Rule the acid <u>hydrogen</u> (H) gets attached to the carbon with more hydrogen substituents, and the <u>halide</u> (X) group gets attached to the carbon with more alkyl substituents) (Markovnikov¹ s Rule)

$$CH_3-C \equiv CH+HCl \rightarrow CH_3-CCl = CH_2+HCl \rightarrow CH_3-CCl_2-CH_3$$

4- Addition of water (Hydration)

One difference between the acid catalyzed hydration of alkenes and that of alkynes. Alkynes form alcohol Alkynes form compounds containing C=O bond.

$$CH_3-C \equiv CH + H_2O \xrightarrow{H_2SO_4} CH_3-C = CH_2 \xrightarrow{rearrangement} CH_3-C - CH_3$$
