

SHIGELLA AND SALMONELLA

1- SHIGELLA

Genus: *Shigella* , **Familly:** Enterobacteriaceae , **Tribe:** Escherichia , **Genus:** Salmonella

Discovered by **Kiyoshi Shiga** in 1898. , It is the causative agent of **human shigellosis**.

Classification: There are more than **40 serotypes**. The classification of *Shigella* e relies on **biochemical** and **antigenic** characteristics (O antigens). The pathogenic species are *Shigella sonnei*, *Shigella flexneri*, *S. dysenteriae*, and *Shigella boydii*.

Important Properties:

Shigella e are

- **short Gram-negative rods.**
- **non–lactose-fermenting.**
- **Resistant to bile salts**
- **Divided into four groups: A, B, C, and D according to (O) antigen.**

Shigella can be distinguished from **salmonellae** by three criteria:

- They produce **no gas** from the fermentation of **glucose**
- They **do not** produce **H₂S**
- They are **non-motile**.

SHIGELLA AND SALMONELLA

Virulence Factors:

1. K. capsular antigen
2. O. antigen (HL)
3. Shiga toxin: with **cytotoxic** and **neurotoxic** activity.

Pathogenesis of *Shigella* :

- *Shigella* causes **bacillary dysentery** , **Low** infective dose < **200 bacilli** (can be transmitted **easily** unlike salmonella (**More serious and virulent** than salmonella)
- Incubation period = **1-3 days**

SHIGELLA AND SALMONELLA

- Upon ingestion, the bacteria **pass** through the **gastrointestinal** tract until they reach the **small intestine**. There they begin to **multiply** until they reach the **large intestine**. In the large intestine, the bacteria cause cell **injury** and the beginning stages of Shigellosis via two main mechanisms: **direct invasion of epithelial cells** in the large intestine and **production of enterotoxin 1** and **enterotoxin 2**. High fever, chill, abdominal cramp and pain accompanied by tenesmus, bloody stool with mucus & WBC and HUS are involved.

SHIGELLA AND SALMONELLA

Laboratory Diagnosis:

Specimens: include **fresh stool**, **mucus flecks**, and **rectal swabs** for culture. **Large numbers** of **fecal leukocytes** and some red blood cells often are seen microscopically.

Culture: The materials are streaked on differential media (eg, MacConkey or EMB agar) and on selective media (Hektoen enteric agar or xylose-lysine-deoxycholate agar), which suppress other Enterobacteriaceae and Gram-positive organisms.

Colorless (lactose-negative) colonies are inoculated into TSI agar. Organisms that **fail** to produce H_2S , that **produce acid** but **not gas** in the **butt** and an **alkaline** slant in TSI agar medium.

Salmonella *Shigella* (SS) Agar: *Shigella* **Clear, colorless, transparent.**

XLD- Agar: *Shigella flexneri* **Red Colonies**

TSI-Agar: Salmonella **Alkaline** slant/**acidic** butt (K/A); - **H_2S** and **Gas-**

2- Genus: *Salmonella*

Introduction: The organisms are named after the American veterinary pathologist **Daniel Elmer Salmon** in 1885. Currently, there are three recognized species: *S. enterica*, *S. bongori* and *S. subterranean*. Salmonella is found worldwide in cold- and warm-blooded animals (including humans), and in the environment. They cause illnesses such as **typhoid fever**, **paratyphoid fever**, and foodborne illness.

Classification:

- The members of the genus Salmonella were originally classified on the basis of **epidemiology**; **host range**; **biochemical reactions**; and **structures** of the O, H, and Vi (when present) antigens.

SHIGELLA AND SALMONELLA

- *Salmonella* spp. have both H and O antigens. There are over 60 different O antigens, and individual strains may possess several O and H antigens; the latter can exist in variant forms, termed '**phases**'. *Salmonella* serotype **Typhi** also has a **capsular polysaccharide** antigen referred to as 'Vi' (for **virulence**), which is related to **invasiveness**

- Over 2500 serotypes are distinguished, most of which belong to the species *S. enterica*. However, many of these have been given binomial names (e.g. *Salmonella typhimurium* and *Salmonella enteritidis*), although they are not separate species. In clinical practice, laboratories identify microorganisms according to their binomial name.

Important Properties: Salmonellae are **motile** rods that characteristically ferment **glucose** and **mannose** without producing **gas** but do not ferment **lactose** or **sucrose**. Most salmonellae produce **H₂S**. They are often pathogenic for humans or animals when ingested.

Virulence Factors:

1. **Type III secretion systems:** which **facilitate** secretion of virulence factors of *Salmonella* into host cells.

2. **Endotoxin:** Endotoxin is responsible for many of the systemic manifestations of the disease caused by *Salmonella* spp.

3. **Fimbriae:** The species-specific fimbriae **mediate binding** of *Salmonella* to M (microfold) cells present in **Peyer patches** of the **terminal part** of the **small intestine**. These M cells typically **transport** foreign antigens, such as **bacteria** to the underlying **macrophages** for clearance.

SHIGELLA AND SALMONELLA

4. Acid tolerance response gene: The acid tolerance response (ATR) gene protects *Salmonella* spp. from **stomach acids** and the **acidic pH** of the **phagosome**, thereby facilitating survival of bacteria in phagosomes

5. Enzymes: **Catalase** and **superoxide dismutase** are the enzymes that protect the bacteria from **intracellular killing** in **macrophages**.

Pathogenesis of Salmonella: The three types of *Salmonella* infections (**enterocolitis**, **enteric fevers**, and **septicemia** وجود البكتيريا بمجرى الدم وتكاثرها) have different pathogenic features.

(1) **Enterocolitis:** is characterized by an **invasion** of the **epithelial** and **sub-epithelial tissue** of the small and large intestines.

SHIGELLA AND SALMONELLA

(2) In **typhoid** and other **enteric** fevers, infection begins in the **small** intestine, but few **gastrointestinal** symptoms occur.

(3) **Septicemia** accounts for only about 5–10% of *Salmonella* infections and occurs in one of two settings: a patient with an underlying **chronic disease**, such as **sickle cell anemia** or **cancer**, or a child with enterocolitis.

Laboratory Diagnosis:

In enterocolitis: the organism is most easily isolated from a stool sample in selective media e.g. XLD (Xylose lysine deoxycholate agar), DCA (deoxycholate citrate agar), salmonella-*Shigella* (SS) agar, and enrichment media, e.g. **selenite** broth; identification of *Salmonella* spp. by biochemical agglutination tests. Phage typing can be used for typing individual strain.

SHIGELLA AND SALMONELLA

Salmonella *Shigella* (SS) Agar: salmonella **colorless, transparent**, with a **black center** if H_2S is produced

XLD- Agar: *Salmonella* Typhi **red Colonies, black** centers.

TSI-Agar: Salmonella **Alkaline** slant/**acidic** butt (K/A); + H_2S and Gas +.

In the enteric fevers: a **blood culture** is the procedure most likely to reveal the organism during the first weeks of illness. **Stool cultures** may also be positive, especially in **chronic carriers** in whom the organism is secreted in the bile into the intestinal tract. **Urine culture** results may be positive after the second week.

Serologic Methods:

- I. Agglutination test
- II. Tube dilution agglutination test (Widal test): Serum agglutinins rise sharply during the **second** and **third** weeks of S serotype Typhi infection.
